

Incinerators series "DA" controlled combustion

Incinerators series "DA" a dual fuel incineration system environmentally friendly solution for the disposal of solid waste

The incineration by the controlled combustion Incinerators "DA" series takes place according to the most advanced techniques and allows the destruction of waste without causing air pollution and without the need of any purifier.

The Incinerators "DA" series are based on the principle of combustion into two stages: the first takes place in the combustion chamber and the second in the reactor.

Based on this principle the products to be incinerated are subjected to the first stage in the combustion chamber in which the waste is stowed. This phase takes place in air defect, thus giving rise to a process of distillation of the volatile components with a consequent production of gaseous products.

In the second phase these gaseous products, before being evacuated from the chimney, are forced to pass through the reactor, previously heated to the operating temperature and in which flows through the nozzles, the quantity of air necessary for the complete oxidation and full combustion of the products gaseous.

Specialized institutes have proven the incinerator Series "DA" by burning waste of various types, and measuring the emission of solid particles and unburnt gaseous residues.

The emission of solid and gaseous unburned parts was below those required by the air pollution standards.

ADVANTAGES

The main practical advantages that are obtained with the Incinerators controlled combustion Series "DA" can be summarized as follows:

1) No fumes

Due to the integral in the combustion reactor of the combustion products.

2) Sensible saving

Due to the reduction of the manual operations which are limited to the load of the waste and to the extraction of the slag.

The incinerator can be loaded during normal working hours, also acting as a deposit of material to be eliminated, while during the incineration process, which takes place in a completely autonomous and automatic way, does not require assistance and the presence of personnel, for which it can work even during the night hours.

3) Regularity of the operation

Due to the effectiveness of the automatic adjustment of combustion; in fact, once calibrated the operating cycle in dependence of the quality of the waste, the plant will always work in the same way, always providing the same optimal results.

4) Increased cleaning

During operation, the incinerator cannot and should not be opened for the fire government or for further loading for which all the external environment and the incinerator itself remain clean.

OPERATING CYCLE

The operating cycle, fully automatic, is controlled by a programmer device which controls all the specific equipment in a way that enter into operation at the time predetermined.

After that the combustion chamber has been loaded and filled entirely, and after that the loading door sealing has been closed, it gives start to the incineration process that involves the following cyclic phases:

1) At the start controlled by the operator, the programmer device is put into operation the burners of the reactor.

2) Upon reaching the reactor operating temperature (1000 ° C) the adjusting device automatically causes the electric starter that provides the combustion air and the simultaneous ignition of the burner of the combustion chamber.

3) Subsequently, the temperature controllers of the combustion chamber and the reactor, suitably calibrated, will maintain, by means of automatic starting and stopping of the burners, the predetermined temperatures up incineration of all combustible parts.

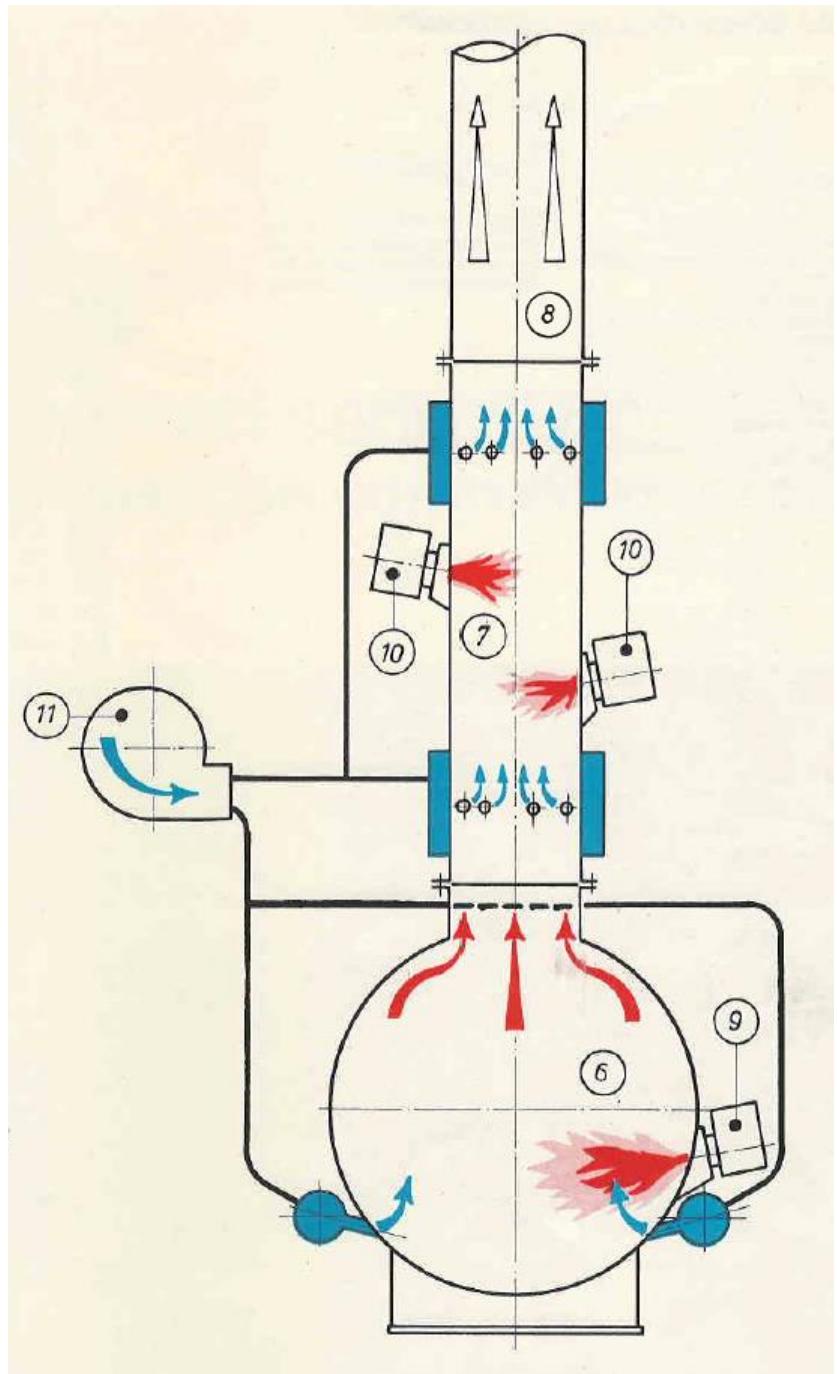

4) At the end of the phase of incineration the programmer causes the disconnection, possibly differentiated, of all the burners while maintaining the air inlet in order to cool the combustion chamber.

5) Once cooled the programmer will cause the automatic shutdown of the electric fan and at this point it will be possible therefore:

- Reopen the oven, remove the slag, stow a new load in the combustion chamber and start another incineration cycle.

N.B.: The period of operation is secured by the programmer that is adjusted in dependence of the quality of waste.
